

# Routing in Dallas - Fort Worth

---

## Overview

- Simulation Model
- Iterative Planning Process
  - Improvement during Iteration
  - Specific Comparison to TRANSIMS
  - Selection of Routes for Re-planning
  - Route-Loss
- Online Routing (Demo)

# Routing in Dallas - Fort Worth

---

## links

- asymmetric CA model
- individual speed limit
- uniform number of lanes (no turning pockets)

## intersections

- blocks to slow down and stop vehicles
- move to destination link if first site is vacant
- preserve order of incoming vehicles

## traffic lights

- activate/deactivate incoming link
- an incoming link has one phase length for all outgoing links
- phase length weighted with the number of outgoing lanes

# Routing in Dallas - Fort Worth

---

## Implementation

- Geometric distribution of network on CPUs
- Links are split at the center as boundaries
- Message passing with PVM or MPI
- Static load-balancing using average execution times of previous iteration as link costs

## Computational Speed

- Real-Time-Ratio is approx. 15 with 8 CPUs on Gershwin
- Clipping time 8 minutes
- Simulation Time 30-40 minutes
- Planning time 10-15 minutes
- Overall time per iteration: 48-63 minutes

# Iterative Routing

---

## Basic Algorithm

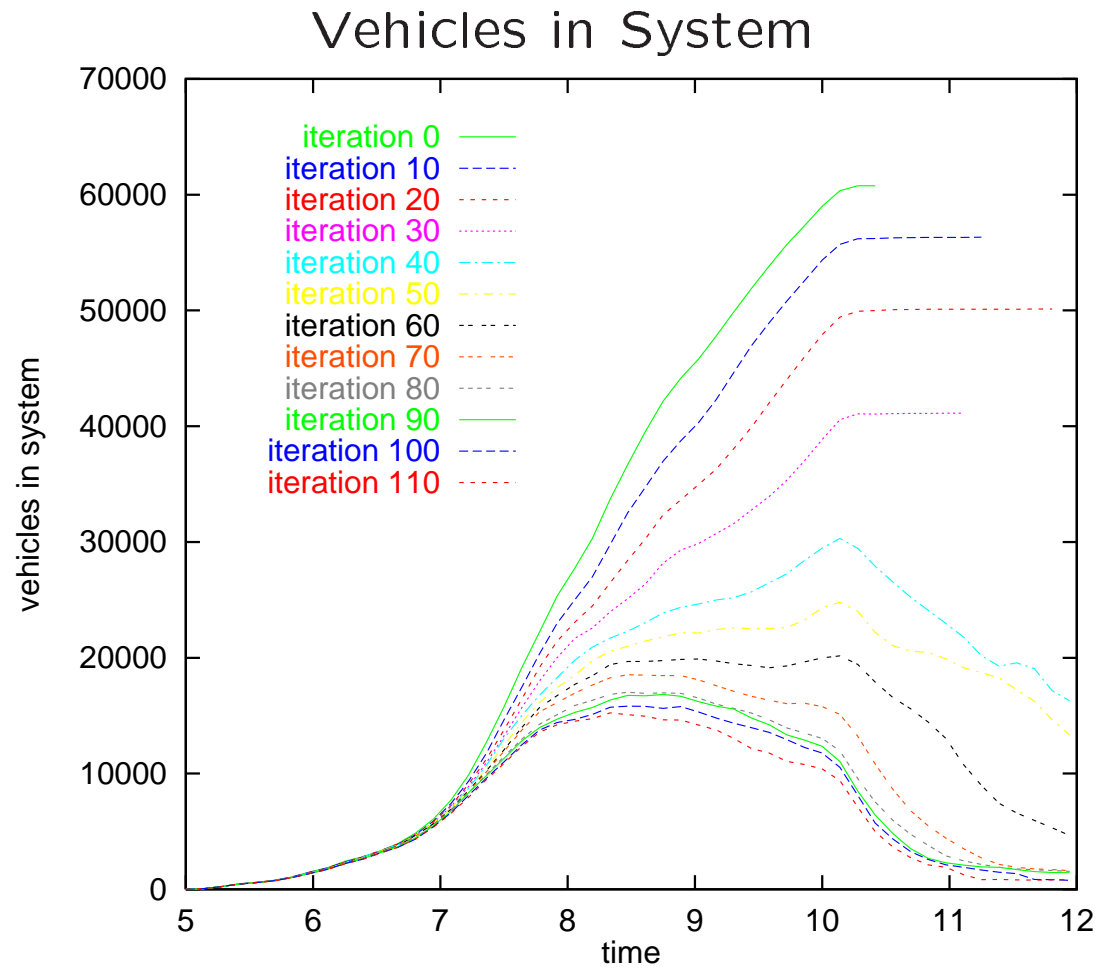

- Start with an initial route-set,
- (\*) Clip routes to study-area using free-flow velocities,
- Run micro-simulation ( $\rightarrow$  link travel times),
- Re-plan fraction  $p_0$  of routes using link travel times,
- Go to (\*) if necessary.

## Current Questions (Not answered by this talk):

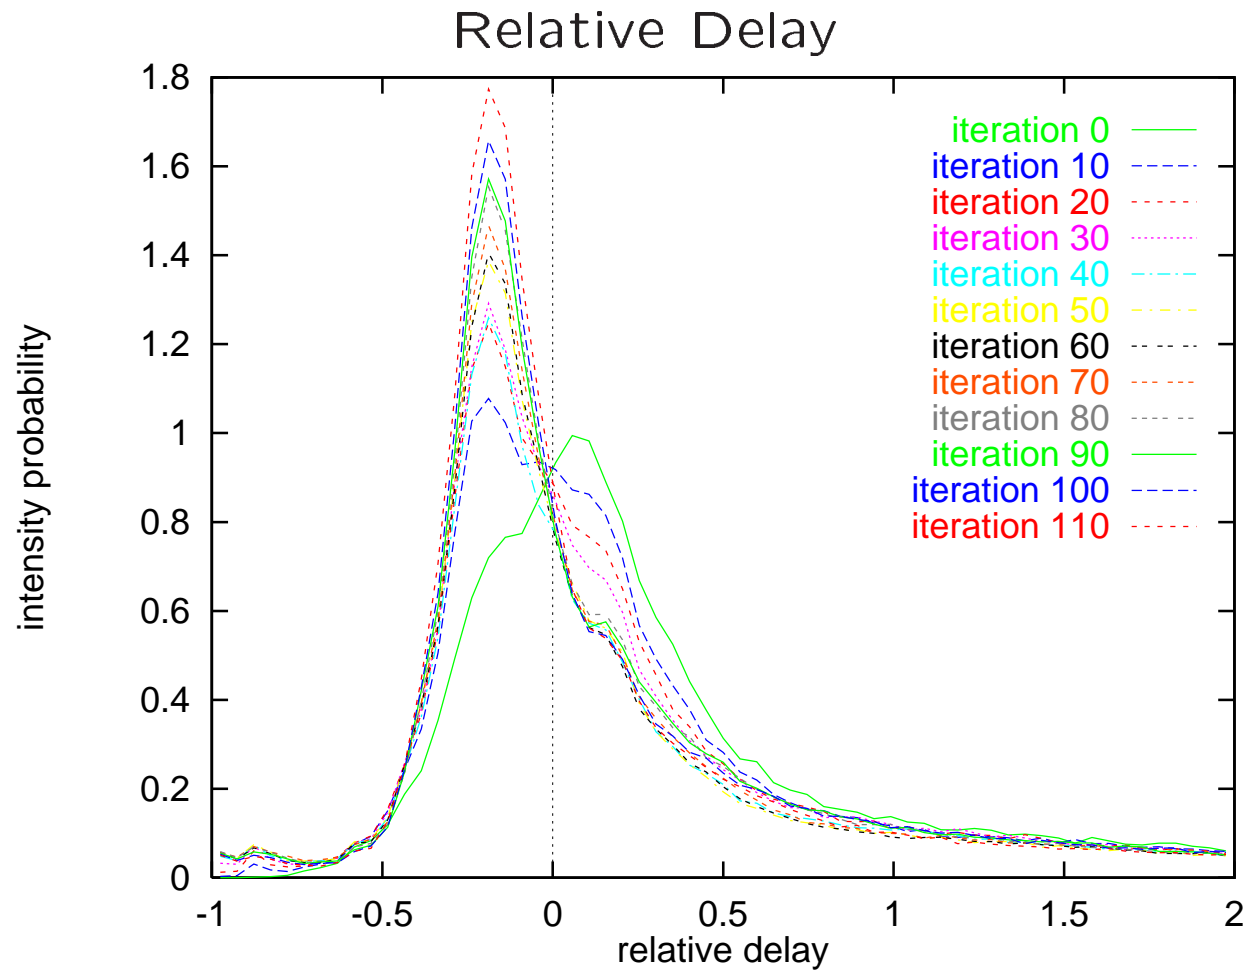

- Which initial route-set?
- What re-planning fraction?
- What subset of routes is to be re-planned?
- How many iterations?

# Iterative Routing

# Iterative Routing

# Iterative Routing

---

Observations:

- situation in studyarea improves because
  - routes are distributed better (grid-locks disappear)
  - routes 'leave' study-area (→ level-0 correction)
- some links are still heavily grid-locked at 10:00 am (→ selection of routes for re-planning)
- about 10.000 vehicles are still in queues at noon (→ queue feedback)

# Iterative Routing

---

## Specific Comparison with TRANSIMS-14 Run

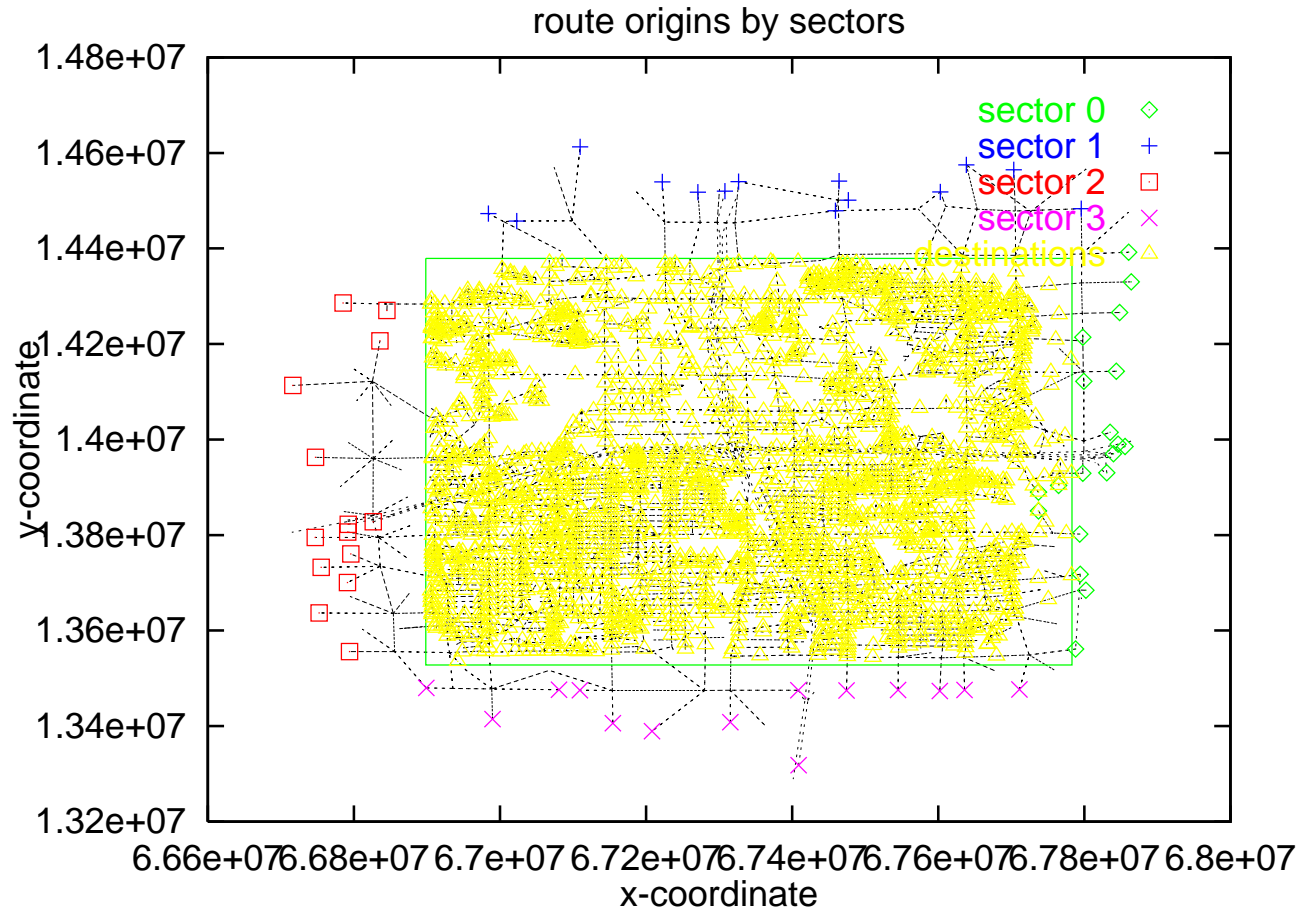

- Look at all routes with destinations inside the study-area.
- For each route store/compute:
  - the source location  $S$  where the route enters,
  - the destination location  $D$ ,
  - the travel-time  $T$  from  $S$  to  $D$ ,
  - the angle between  $S$  and the center of the area,
  - the average travel-velocity using  $T$  and the Euclidian distance between  $S$  and  $D$ .
- Average over all routes / all routes from each sector (north, south, east, west)

---

## Selection of Routes for Re-planning

- random:  $p(a) = p_0$
- constant: replan constant number of original plan-set
- age dependant:  $p(a) = qa$

# Iterative Routing

## Routes in Study-Area

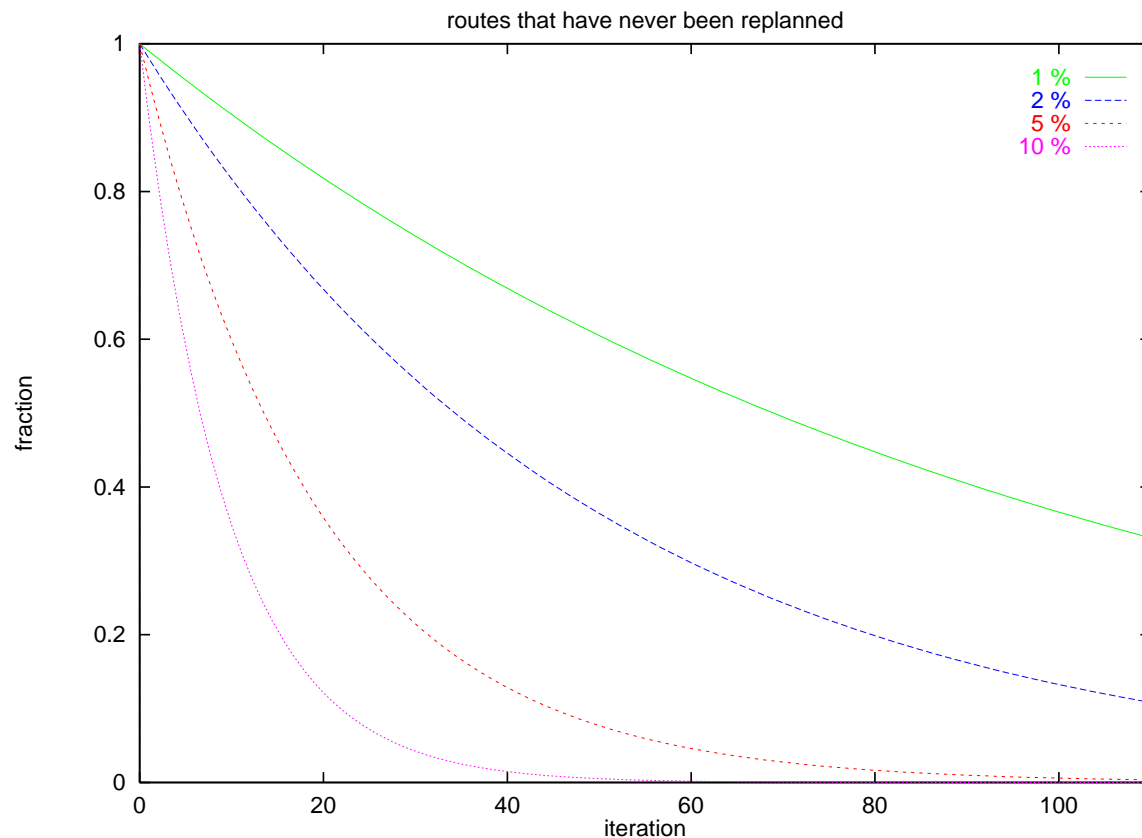

# Iterative Routing

## Vehicles in Study-Area

# Iterative Routing

Problem with random selection: large probability not to be re-planned for small re-planning fraction  $p_0$  even after many iterations  $n$ :

# Iterative Routing

---

Age-dependant Re-planning

**Idea:** old plans are to be planned sooner:  $p(a) = qa$

This leads to an ansatz for the age distribution:

$$f(a + \Delta a) = f(a) - p(a)f(a)\Delta a$$

$$f(a) = p_0 e^{-\pi/4 p_0^2 a^2} \quad \text{normal distribution}$$

## Comparison of Aging Process

# Iterative Routing

---

Route Loss: Is it OK? Too many routes anyway?

If it is not, how to prevent it?

**Idea:** make links outside the study area look similar (= as bad) as those inside the area (“level-0 correction”).

**good:** reduces loss of plans avoiding the study-area “space-wise”

**bad:** spreads entry times over a time period → loss of plans through time-window

Possible Fix: setting arrival-time instead of departure-time.

# Iterative Routing

## Routes Lost Through Level-0 Correction

# Online Routing

---

## Basic Algorithm

- Collect every 10 time-steps
- Average and broadcast every 120 time-steps
- Select fraction (10%) of travellers by route-ID to have access to route-guidance
- Compare current travel time estimate to the one computed by the planner
- If relative delay  $>$  threshold (0.5)  $\rightarrow$  **compute shortest path** with Dijkstra based upon current link travel times
- If relative improvement  $>$  threshold (0.2)  $\rightarrow$  **update route**

# Online Routing
